

Hubble Space Telescope Servicing Mission 3B Media Reference Guide

**Special thanks to everyone who
helped pull this book together.**

**Buddy Nelson – Chief writer/editor
Mel Higashi – Design and layout
Pat Sharp – Text and graphics integration**

**Computer generated 3-D illustrations provided by
Tim Cole, Kevin Balch, David Green, Nick Dellwo**

**Background information provided by
Brian Woodworth, Donna Weaver, Ann Jenkins,
Monty Boyd, Ray Villard, Dave Leckrone**

**Prepared by Lockheed Martin for
the National Aeronautics and Space Administration**

Who Was Edwin P. Hubble?

Photo courtesy of the Carnegie Institution of Washington

Edwin Hubble (1889–1953) at the 48-inch Schmidt telescope on Palomar Mountain

One of the great pioneers of modern astronomy, the American astronomer Edwin Powell Hubble (1889–1953), started out by getting a law degree and serving in World War I. However, after practicing law for one year, he decided to “chuck law for astronomy and I knew that, even if I were second rate or third rate, it was astronomy that mattered.”

He completed a Ph.D. thesis on the Photographic Investigation of Faint Nebulae at the University of Chicago and then continued his work at Mount Wilson Observatory, studying the faint patches of luminous “fog” or nebulae in the night sky.

Using the largest telescope of its day, a 2.5-m reflector, he studied Andromeda and a number of other nebulae and proved that they were other star systems (galaxies) similar to our own Milky Way.

He devised the classification scheme for galaxies that is still in use today, and obtained extensive evidence that the laws of physics outside the Galaxy are the same as on Earth—in his own words: “verifying the principle of the uniformity of nature.”

In 1929, Hubble analyzed the speeds of recession of a number of galaxies and showed that the speed at which a galaxy moves away from us is proportional to its distance (Hubble’s Law). This discovery of the expanding universe marked the birth of the “Big Bang Theory” and is one of the greatest triumphs of 20th-century astronomy.

In fact, Hubble’s remarkable discovery could have been predicted some 10 years earlier by none other than Albert Einstein. In 1917, Einstein applied his newly developed General Theory of Relativity to the problem of the universe as a whole. Einstein was very disturbed to discover that his theory predicted that the universe could not be static, but had to either expand or contract. Einstein found this prediction so unbelievable that he went back and modified his original theory in order to avoid this problem. Upon learning of Hubble’s discoveries, Einstein later referred to this as “the biggest blunder of my life.”

Another Step in Our Journey to the Stars

Throughout history, humankind has expanded its knowledge of the universe by studying the stars. Great scientists such as Nicholas Copernicus, Galileo Galilei, Johannes Kepler, Issac Newton, Edwin Hubble and Albert Einstein contributed significantly to our understanding of the universe.

The launch of the Hubble Space Telescope in 1990 signified another great step toward unraveling the mysteries of space. Spectacular discoveries such as massive black holes at the center of galaxies, the existence of precursor planetary systems like our own, and the quantity and distribution of cold dark matter are just a few examples of the Telescope's findings.

With NASA's Servicing Mission 3B, we continue to carry the quest for knowledge in the 21st century.

About the Inside Covers

Three-dimensional computer models illustrate tasks that the STS-109 crew will perform in orbit during Servicing Mission 3B. The models enable engineers to study task feasibility and to confirm that astronauts can safely reach and service components and locations on the spacecraft. These dimensionally accurate, visually correct images help the extravehicular activity servicing team prepare to install new components and upgrade functional systems on the Telescope.
